

## **Business Understanding**

The Seattle government is going to prevent avoidable car accidents by employing methods that alert drivers, health system, and police to remind them to be more careful in critical situations. In most cases, not paying enough attention during driving, abusing drugs and alcohol or driving at very high speed are the main causes of occurring accidents that can be prevented by enacting harsher regulations. Besides the aforementioned reasons, weather, visibility, or road conditions are the major uncontrollable factors that can be prevented by revealing hidden patterns in the data and announcing warning to the local government, police and drivers on the targeted roads. The target audience of the project is local Seattle government, police, rescue groups, and last but not least, car insurance institutes.

The model and its results are going to provide some advice for the target audience to make insightful decisions for reducing the number of accidents and injuries for the city. Data The data was collected by the Seattle Police Department and Accident Traffic Records Department from 2004 to present.

## **Data**

The data consists of 37 independent variables and 194,673 rows. The dependent variable, “SEVERITYCODE”, contains numbers that correspond to different levels of severity caused by an accident from 0 to 4.

Severity codes are as follows: 9/2/2020 Seattle Car Accident Severity. IBM Data Probability (Clear Conditions)

- 1: Very Low Probability — Chance or Property Damage
- 2: Low Probability — Chance of Injury
- 3: Mild Probability — Chance of Serious Injury
- 4: High Probability — Chance of Fatality Furthermore, because of the existence of null values in some records, the data needs to be preprocessed before any further processing.

## **Data Preprocessing**

The dataset in the original form is not ready for data analysis. In order to prepare the data, first, we need to drop the non-relevant columns. In addition, most of the features are of object data types that need to be converted into numerical data types. After analyzing the data set, I have decided to focus on only four features,

severity, weather conditions, road conditions, and light conditions, among others. To get a good understanding of the dataset, I have checked different values in the features. The results show, the target feature is imbalance, so we use a simple statistical technique to balance it. As you can see, the number of rows in class 1 is almost three times bigger than the number of rows in class 2. It is possible to solve the issue by downsampling the class 1.

## **Methodology**

For implementing the solution, I have used Github as a repository and running Jupyter Notebook to preprocess data and build Machine Learning models. Regarding coding, I have used Python and its popular packages such as Pandas, NumPy and Sklearn.

Once I have load data into Pandas Dataframe, used 'dtypes' attribute to check the feature names and their data types. Then I have selected the most important features to predict the severity of accidents in Seattle. Among all the features, the following features have the most influence in the accuracy of the predictions:

- "WEATHER",
- "ROADCOND",
- "LIGHTCOND"

Also, as I mentioned earlier, "SEVERITYCODE" is the target variable.

I have run a value count on road ('ROADCOND') and weather condition ('WEATHER') to get ideas of the different road and weather conditions. I also have run a value count on light condition ('LIGHTCOND'), to see the breakdowns of accidents occurring during the different light conditions.

After balancing SEVERITYCODE feature, and standardizing the input feature, the data has been ready for building machine learning models.

I have employed three machine learning models:

- K Nearest Neighbour (KNN)
- Decision Tree
- Linear Regression

After importing necessary packages and splitting preprocessed data into test and train sets, for each machine learning model, I have built and evaluated the model and shown the results as follow:

## K nearest neighbours

```
1 from sklearn.neighbors import KNeighborsClassifier
2 k = 17
3 knn = KNeighborsClassifier(n_neighbors = k).fit(X_train,y_train)
4
5 knn_y_pred = knn.predict(X_test)
6 knn_y_pred[0:5]
```

```
array([2, 2, 1, 1, 2], dtype=int64)
```

## KNN Evaluation

### KNN Evaluation

```
1 jaccard_score(y_test, knn_y_pred)
```

```
0.3091637411108111
```

```
1 f1_score(y_test, knn_y_pred, average='macro')
```

```
0.5477714681769319
```

## Decision tree

## Decision Tree

```
1 from sklearn.tree import DecisionTreeClassifier
2 dt = DecisionTreeClassifier(criterion="entropy", max_depth = 7)
3
4 dt.fit(X_train,y_train)
```

DecisionTreeClassifier(criterion='entropy', max\_depth=7)

```
1 dt_y_pred = dt.predict(X_test)
```

## Decision Tree Evaluation

```
1 jaccard_score(y_test, dt_y_pred)
```

0.2873687679487783

```
1 f1_score(y_test, dt_y_pred, average='macro')
```

0.5450597937389444

## Liner Regression

## Linear Regression

```
1 from sklearn.linear_model import LogisticRegression
2 from sklearn.metrics import confusion_matrix
3 LR = LogisticRegression(C=6, solver='liblinear').fit(X_tr
```

```
1 LR_y_pred = LR.predict(X_test)
```

```
1 LR_y_prob = LR.predict_proba(X_test)
```

```
1 LR_y_prob = LR.predict_proba(X_test)
2 log_loss(y_test, LR_y_prob)
```

0.6849535383198887

## Linear Regression Evaluation

```
1 jaccard_score(y_test, LR_y_pred)
```

0.2720073907879108

Evaluations The final results of the model evaluations are summarized in the following table:

ML Model	Jaccard Score	F1 Score	Accuracy
KNN	0.30	0.55	0.56
Decision Tree	0.28	0.54	0.57
Linear Regression	0.27	0.51	0.53

Based on the above table, KNN is the best model to predict car accident severity.

## **Conclusion**

Based on the dataset provided for this capstone from weather, road, and light conditions pointing to certain classes, we can conclude that particular conditions have a somewhat impact on whether or not travel could result in property damage (class 1) or injury (class 2).
